Assessment Part 2

Integrate Data Storage

1. A DynamoDB table named **coupons** is registered in **localstack**.

   The DynamoDB table should be configured to support the following requirements:

   - Perform 50 eventually consistent reads per second
   - Perform 10 eventually consistent writes per second
   - The average item size is 1 Kilobyte.
2. The lambda function **coupons_get_by_id** is updated to retrieve the coupons from the database given their id. The coupon id will be passed in from the API Gateway as a path parameter.
3. The **coupons_get_by_id** lambda function will receive an event from the API Gateway that contains the coupon id in the form of a path parameter named id and return the coupon matching the identifier.
4. The lambda function named **coupons_update** is updated to update coupons in the database given their id. The coupon id will be passed in from the API Gateway as a path parameter named id. The DynamoDB table is updated with a new index that allows for performant queries using the fields **provider_id** and **campaign_id**.

Submission:

1. Write down all the commands into a txt file and name it as "**Command.txt**"
2. Push your project folder into GitHub, including all **your project files** and output.
3. Make a recording of running your project and show the outcome.
4. Submit the video into D2L dropbox and past your GitHub link into comment.
